Problem Summary

- Given the root of a binary tree, return the postorder traversal of its nodes' values

Post order means left → right → root

Key Idea

Visit both subtrees first, then visit the current node last.

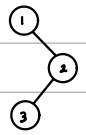
So the order is always:

→ left child

→ right child

→ current node

Diagram Examples



3 → 2 → 1

Approach

1) Create an empty result list

2) Define a helper function postorder (node)

3) If node is None, return

4) Recurse on left subtree

5) Recurse on right subtree

6) Add node value to result

7) Call postorder (root)

8) Return result

Time Complexity : O(n) → Each node is visited once

Space Complexity : O(h) → Recursion stack, where h is tree height + O(n) because result stores the values of all nodes
