Problem Summary

- Given the root of a binary tree, return the in order traversal of its nodes' values

In order means left → root → right

Key Idea

Visit the left subtree first,

then visit the current node,

then visit the right subtree

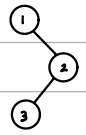
So the order is always:

→ left child

→ current node

→ right child

Diagram Examples



1 → 3 → 2

Approach

1) Create an empty result list

2) Define a helper function inorder(node)

3) If node is None, return

4) Recurse on left subtree

5) Add node value to result

6) Recurse on right subtree

7) Call inorder(root)

8) Return result

Time Complexity : O(n) → Each node is visited once

Space Complexity : O(h) → Recursion stack, where h is tree height + O(n) because result stores the values of all nodes
